EXECUTIVE SUMMARY

The Miami Harbor Phase III Federal Channel Expansion Project was designed to widen and deepen the outer entrance channel to increase access to the Port of Miami by larger vessels, including post-Panamax vessels. The project was permitted through the Florida Department of Protection (FDEP), under Permit No. 0305721-001-BI. Permit conditions provide a number of protective measures to ensure the preservation of natural resources, such as hardbottom, reef, and seagrass communities, including methods on environmental monitoring required before, during, and after dredging activities.

The following baseline report establishes information on the population dynamics, condition and sedimentation environment of the middle and outer reef benthic communities adjacent to the Miami Harbor Phase III Federal Channel Expansion Project area. These baseline results will be used as a point of comparison for the post-construction survey to document changes to coral reef communities attributable to project activities.

Middle reef sites included four compliance sites (R2N1-RR, R2N2-LR, R2S1-RR, and R2S2-LR) and five control sites (R2NC1-LR, R2NC2-RR, R2NC3-LR, R2SC1-RR, R2SC2-LR). Outer reef sites included four compliance sites (R3N1-LR, R3S1-CP, R3S2-LR, and R3S3-SG) and four control sites (R3NC1-LR, R3SC1-CP, R3SC2-LR, and R3SC3-SG). Three, 20m permanent transects, with up to 10 permanently marked corals, were established at each site. A total of 51 transects covering 1020m^2 of middle and outer reef habitats were surveyed over a four week period during the baseline assessment. Abiotic and biotic characteristics, including: substrate composition, abundance, density, size frequency and diversity of scleractinian corals and octocorals, scleractinian coral condition, sponge and zoanthid density, functional group percent cover, and baseline sedimentation rates were documented at each monitoring site during the baseline survey. Photos of all permanently marked corals and video of each transect were also collected. Parametric and non-parametric statistics were used to analyze the abundance and density of scleractinians and octocorals, as well as condition of corals at middle and outer reef sites.

Middle reef sites included 11-17 coral species, with colony density ranging from 0.95 to 2.49 colonies per square meter across all sites. The greatest proportions of corals were in the 10-15 cm size range. Coral stress was indicated in 53.2% of middle reef corals with sediment stress, polyp extension, fish bites, excess mucus, and unknown partial mortality being the most frequent stress indiciators at middle reef sites. Eight to ten genera of octocorals were present across middle reefs sites and density ranged from 1.83 to 11.88 colonies per square meter. Octocorals were most commonly in the 5-20 cm size range across all middle reef sites. The top three cover functional group categories were crustose turf and bare (CTB), octocorals, and zoanthids at middle reef sites.

Outer reef sites included 10-15 coral species, with colony density ranging from 1.03 to 3.51 colonies per square meter across all sites. The greatest proportion of coral colonies at outer reef sites were in the 10-15 cm size range. Coral stress was indicated in 52.3% of outer reef corals with sediment stress, polyp extension, fish bites, excess mucus, and unknown disease being the most frequent stress indicators at outer reef sites. Four to seven octocoral genera were identified at outer reef sites and octocoral density ranged from 1-8 colonies per square meter across outer reef sites. Octocorals of the 5-20 cm size range were most common across all outer reef sites. The top three functional group categories at outer reef sites were CTB, octocorals, and sponges.

Throughout the project area, numerous colonies of coral *Solenastrea bournoni* started to show outward signs of distress in the late fall of 2013. This included disease-like symptoms with mottled coloration and necrotic tissues. As many as 6% of corals at middle and outer reef survey sites were documented with this unknown disease during baseline surveys. Marked corals exhibiting these symptoms are being followed to understand the spread and causality of this coral malady and its impacts on the overall health of the ecosystem.

Baseline quantitative sediment sampling results from quantitative sediment sample collection at middle and outer reef sites documented different daily sedimentation rates between reef areas (middle and outer) and between channel-side and reference sites. Middle reef sites daily sedimentation rates were higher than outer reef rates for both coarse ((≥ 230 sieve fraction) and fine (≤ 230 sieve fraction) material. Channel-side sedimentation rates were similar to reference site rates at middle reef southern sites and outer reef sites. Northern middle reef channel-side sedimentation rates were higher than northern middle reef reference sites. Channel-side sites may have different sedimentation rates when compared to reference sites since the water quality and hydrodynamics of channel-side sites are different than their natural reef reference counterparts.

1.0 INTRODUCTION

1.1 Study Context and Objectives

The Miami Harbor Phase III Federal Channel Expansion Project was designed to widen and deepen the outer entrance channel to increase access to the Port of Miami by larger vessels, including post-Panamax vessels. To accommodate these larger vessels, the outer entrance channel is proposed to be widened at the outer reef and deepened to -52 (+1) feet Mean Lower Low Water (MLLW) (-15.6 ± 0.3 m). Avoidance and minimization of impacts to natural resources (hardbottom, coral reef, and seagrasses) was conducted through the NEPA process and a Record of Decision was signed on May 22, 2006. The project was permitted through the Florida Department of Protection (FDEP), under Permit No. 0305721-001-BI (issued on May 22, 2012). Permit conditions provide a number of protective measures to ensure the preservation of natural resources, such as hardbottom, reef, and seagrass communities, including methods on environmental monitoring required before, during, and after dredging activities.

Great Lakes Dredge and Dock (GLDD) is responsible for implementing the required environmental monitoring program during the immediate pre-, during, and immediate post-construction time periods associated with the Miami Harbor Phase III Federal Channel Expansion Project.

Dial Cordy and Associates Inc. (DCA) was contracted by GLDD to conduct baseline and compliance monitoring of hardbottom, reef, and seagrass habitats in the project area. Specifically, DCA was contracted to (1) conduct baseline surveys at hardbottom, middle and outer reef monitoring sites, and their reference sites (2) conduct compliance monitoring at hardbottom, middle and outer reef sites (3) conduct baseline surveys at Fisherman's Channel seagrass sites (4) conduct compliance monitoring at Fisherman's Channel seagrass sites (5) conduct baseline surveys at Julia Tuttle Seagrass Mitigation Site (JTSMS) and (6) conduct compliance monitoring at JTSMS.

This report further characterizes the benthic communities within the channel-side (indirectly-affected) areas of the middle and outer reef zones prior to and during project commencement. In addition to serving as a baseline characterization of these areas, the study was designed so that pre- and post-construction results may be compared to detect effects of dredging on adjacent benthic resources. A number of parameters including benthic organism density, cover, and condition, as well as quantitative sedimentation rates will be measured to test the following null hypothesis (H_o):

> H_o: Benthic communities in the indirect effect (channel-side) sites will remain unchanged between the pre- and post-dredging surveys.

1.2   Study Area

The Holocene relict reefs in Miami–Dade County run almost continuously in a generally north-to-south direction along the coast to approximately 55th Street, Miami Beach. A break in the reef ridges occurs at approximately 55th street. South of 55th Street, only two reefs lines run parallel to the coast and are commonly referred to as the second (middle) and third (outer) reefs, with patchy nearshore hardbottom areas lying west of the second reef tract (e.g., Moyer et al. 2003; Figure 1). Today, these nearshore hardbottom areas (patch reefs) and parallel ridges or reefs are dominated by macroalgae, octocorals, sponges, and to a lesser extent hard corals (Moyer et al. 2003, Gilliam 2007).

1.3   Previous Studies

A number of U. S. Army Corps of Engineers (USACE) studies have been conducted to support the project, starting with the Environmental Impact Statement (EIS), which was finalized in 2005. More recently, a Pilot Study was conducted in October 2009 to determine the level of effort required to adequately sample the hardbottom and reef habitats surrounding the Miami channel in order to detect a level of change in functional group cover of 5% (see Dial Cordy and Associates 2010).

Indirect-effect sites and reference sites sampled during the Pilot Study were similar to other reef areas in southeastern Florida that have been characterized by Gilliam (2007), Moyer et al. (2003), and others. In general, these areas are dominated by macroalgae (45–82% cover across sites), with lower cover of other biological groups, including corals (scleractinians and *Millepora*; 0.05–4.62% cover), sponges (0.54–6% cover), and octocorals (1 to 15% cover). The rubble, sand, and pavement group (4–71% cover) was the second most dominant cover type after macroalgae.

1.3.1   Pilot Study Results

The Pilot Study documented that an ANOVA based approach would not provide sufficient statistical power to detect change at the level of 5% across groups (octocorals, macroalgae, corals, and sponges). The sample sizes required to detect a 5% change in macroalgal cover at $P = 0.05$ with a power of 0.80 ranged from 275 to 450 transects per site. Octocoral variances were also high. The sample sizes required to detect a 5% change at $P = 0.05$ with a power of 0.80 for octocorals would start at 2,200 transects per sample site. These results showed that an ANOVA approach is not practical for sampling in this variable and patchy environment. Thus a regression based study design was recommended for quantitatively comparing before and after dredging results.

1.3.2   Quantitative Study Results 2010

Due to the low cover and sporadic occurrence of hard corals and octocorals at the Pilot Study sites, a regression-based approach on the middle and outer reefs, beginning adjacent to the channel, was conducted for the Quantitative Study Plan in 2010. For nearshore hardbottom communities west of the middle reef, a stratified random approach was used, based upon octocoral and scleractinian colony density within treatment and control sites identified during the Pilot Study. The report also recommended that all areas be sampled

using colony counts rather than estimates of cover, due to the low cover of benthic organisms (see also Smith et al. 2011).

By following this recommended design, post-construction surveys conducted after the dredging operation would allow comparison with the pre-dredging data. Effects of the dredging operation on the middle and outer reefs, should they occur, would be detectable as a significant difference between the pre- and post-dredging conditions in the relationship between distance from the channel and the magnitude of change. Effects on hardbottom sites would be detectable as significant interaction terms of ANOVA between time (before *versus* after dredging) and treatment (indirect-effect *versus* reference).

1.3.3 Baseline Quantitative Study 2013

The current study design, permitted by FDEP, was developed using a repeated measures design, with three permanent transects established at each of 26 sites. The study requires a pre-dredging survey and a post-dredging survey, which will be compared after dredging to detect project effects. After the post-construction survey, pre and post survey results will be compared using parametric and non-parametric statistics. This document reports the pre-dredging baseline survey results for middle and outer reef environments.

1.3.4 Corps Survey Results

U.S. Army Corps pre-bid and pre-dredge hydrographic surveys documented differences in sediment accumulation across Cuts 1 and 2 of the federal channel. The nearshore hardbottom habitat, where seven project monitoring survey sites are located, had an 18% increase in sedimentation between August 2010 and October 2013, whereas other locations in Cuts 1 and 2 had a 2-3% increase in sedimentation (personal communication Terri Jordan-Sellers, Feb 13, 2014).

2.0   METHODS

The middle and outer reef baseline survey presents information on the population dynamics, condition and sedimentation environment of the benthic communities adjacent to the Miami Harbor Phase III Federal Channel Expansion Project area. These baseline results will be used as a point of comparison for the post-construction survey to document changes attributable to dredging while considering other environmental or anthropogenic factors that influence hardbottom resources in the area. Appendices as required by specification and contract are included as follows: Appendix A (Raw Data), Appendix B (Photograph), Appendix C (Video). The following section describes the materials and methods used to collect baseline data on the benthic organisms and sedimentation rates at middle and outer reef sites.

2.1   Study Site Selection and Description

In order to evaluate potential construction related impacts associated with the Miami Harbor Phase III Federal Channel Expansion Project across all habitat types on the middle and outer

reef, a total of seventeen sites were designated for monitoring in the state permit. Habitat types were established by Walker (2008) (Figure 1).

Site selection was conducted on a desktop computer, using ArcView™. FDEP permit site polygons were imported into ArcView™. A smaller polygon, fitting within the FDEP polygon, was generated in ArcView™. The ArcView™ random point generator was used to establish a center point for the monitoring site within that smaller polygon.

In the field, HYPACK Navigational™ software was used to locate and mark the center point defined in ArcView™. Scientific divers qualitatively assessed the potential site for the appropriated habitat, including hard corals, and octocorals. The buoy location was adjusted by divers to optimize the amount of reef and/or hardbottom habitat. Thus transect placement was not random, instead transects were intentionally placed in areas devoid of sand where possible. This was done in order to maximize sampling hardbottom or reef habitat, as this was the goal of the monitoring program outlined by the FDEP permit. Transects were established approximately 5 m apart from each other.

2.1.1   Control sites

A total of nine reference sites (controls) were established for comparison with middle and outer reef compliance (channel-side) sites. Five reference sites were established for the middle reef, three in the north (9.38 km away from the channel), two sites in the linear reef (LR) habitat type, and one in the ridge reef (RR) habitat type. Two southern middle reef reference sites were established in the LR and RR habitat types, 1.27 km away from the channel. Four outer reef reference sites were established north and south of the channel; in the north, one representing the LR habitat type was established 9.38 km away from the channel and three southern reference sites representing colonized pavement (CP), LR, and spur and groove (SG) habitat types were 1.3 km away from the channel. The northern reference sites were placed north of the Port anchorage area to avoid confounding effects due to non-project activities at the anchorage.

2.1.2   Channel-side compliance sites

A total of eight channel-side or compliance sites were established approximately 10 m from the edge of the existing channel edge on the middle reef and 10m from the edge of the proposed reef on the outer reef. Four middle reef sites, two on the north side (R2N1-RR and R2N2-LR) and two on the south side (R2S1-RR and R2S2-LR). Outer reef channel-side sites included one site on the north side (R3N1-LR) and three on the south side (R3S1-CP, R3S2-LR, and R3S3-SG).

2.2 Site Layout and Installation

Monitoring site installation was completed in September and October 2013. At each monitoring site, three permanent 20 m transects were established, parallel to each other in a north (0 m) to south (20m) direction (Figure 2). Transect number increases from east to west (1-3) at each site. Stainless steel eyebolts (3/8-in. by 8-in.) were drilled into the bottom at 0, 10, and 20 m locations along each transect. Small closed-cell foam floats coated with anti-fouling paint were attached to each eyebolt with a short length of nylon braided line to aid in transect relocation. Two floats mark the beginning of each transect, while mid and end points are marked with a single float. This provides the diver with an orientation while deploying transect tapes during each monitoring dive. Sediment blocks

Figure 2: Hardbottom monitoring site layout.

were positioned at the center of the site, between Transect 1 and 2. Adjustments to exact transect placement in the field were conducted based on avoiding sand areas, maximizing coral reef and/or hardbottom, and maximizing the number of hard corals on a single transect. HYPACK Navigational™ software was used to record the geographic location of the site center point, and start and end points of all transects at all sites.

2.2.1 Sedimentation Traps

Three sediment traps (Figure 3) were placed at each of the middle and outer reef monitoring sites (including control sites) to allow the comparison of net sediment accumulation among monitoring stations and between construction monitoring sites and reference monitoring sites. The sediment traps are constructed of 1 in. interior diameter x 8 in. interior length polyvinyl chloride (PVC) pipe and a 500-ml Nalgene collection jar, or similar, making modifications to best sample sedimentation within the environment, based on hydrodynamics, currents and particle size (Storlazzi et al. 2011) (Figure 3). Both trap necks and jars are coated with anti-fouling paint to minimize epibiotic growth. The PVC traps with the attached jar lids are fastened to the steel sediment trap frame with hose clamps. The frames are drilled and cemented into the substrate at all

Figure 3: Sediment traps installed at all offshore sites for environmental monitoring of hardbottom and reef resources in Cuts 1 and 2.

hardbottom sites, and are installed to collect sediment from the water column approximately 18 inches off the bottom. Sediment traps are removed at 28-day intervals by unscrewing the Nalgene trap jars from the PVC collars and capping the jars *in situ*. New jars are installed when collections are made and a new 28 day sediment monitoring period begins. Following completion of the monitoring program, all sediment traps, frames, and blocks will be removed.

2.2.2 Sedimentation Blocks

A net sediment accumulation block was placed at each site at the 10 m mark on Transect 2 (Figure 4). This block serves as the center point of the monitoring sites for underwater navigation purposes. The sediment accumulation block consists of an 8 in. x 8 in. x 8 in. concrete block attached to the bottom with hydraulic cement. The block has one side coated with antifouling paint, which is oriented as the upper surface. The antifouling paint minimizes the bioaccumulation on the upper surface of the block which could interfere with sediment accumulation. Blocks were attached to exposed rock surfaces devoid of benthic fauna and no closer than 30 cm to any coral colony to assure no impact to living marine resources from the antifouling paint.
Figure 4: Sediment block used to monitor sediment accumulation at hardbottom and reef resources at offshore sites.

2.3 Data Collection

Baseline surveys of the middle and outer reef sites were conducted over 11 weeks between October 18 and December 30, 2013. Each site was surveyed between 2 and 4 times during the baseline study period, depending on the ability to survey due to adverse weather conditions (Table 1). Adverse weather conditions affected the ability to conduct scientific diving on 41 of 74 days during the baseline monitoring period. Surveys were conducted in order to ensure distinct sampling periods were completed for each site. Baseline sediment trap samples (28-49 days) were collected at all middle and outer reef sites between November 18, 2013 and February 17, 2014.

Small craft advisories were issued during baseline period between October 24-31, November 3-6, 9-10, 14-16, 22, 25-30, and December 1, 8-9, 13, 16, and 19-29. Safe scientific diving operations were not feasible at these times. Safe diving conditions are described in EM-385 (EM-385 is the safety regulation document that guides all USACE scientific diving operations) as current speed of <1 knot and visibility >3 feet; additionally best professional judgment of wind and wave conditions is used to determine whether or not scientific dive operations may be conducted safely.

Table 1: Baseline surveys were conducted at middle reef and outer reef sites between October 23 and December 30, 2013. Weeks in which adverse weather conditions prevented baseline data collection are noted in the table below as "NA".

Site	Week 1	Week 2	Week 3	Week 4

2.3.1 Abiotic Characteristics

Abiotic data were collected to describe the general conditions of each monitoring site. Documentation was collected on the presence of hardbottom, rock, rubble, sand, sedimentation, bare substrate, and maximum water depth.

2.3.2 *In Situ* Data

2.3.2.1 Quality Assurance and Quality Control

All scientific divers were trained and qualified to conduct benthic surveys in middle and outer coral reef environments, per the FDEP permit specifications. During Week 1 of baseline surveys, all scientific divers responsible for collecting *in situ* data participated in quality assurance and quality control training and exercises, with periodic follow-up to maintain QA/QC standards over the life of the project. A buddy pair collected scleractinian species data independently along the same transect and surfaced to compare results. Another buddy pair collected octocoral genera data along the same transect and surfaced to compare results. The octocoral team members had 100% agreement in differentiating octocoral genera. The coral species team had 85% agreement. Questions arose between the identification *Siderastrea siderea* and *S. radians* (3 cm and smaller) and between *Solenastrea bournoni* and *Stephanocoenia intersepta* (5 cm and smaller). The Humann (2002) reef identification guide was referenced and discussions between team members were conducted to assure that future monitoring and data collection was collected with a

common understanding of the benthos being monitored. Subsequent data collection resulted in a 95% agreement between the coral collection team observations. Previous studies have documented difficulty in differentiating corals smaller than 4 cm (Edmunds et al. 1998). As a result of inter-observer variability, data on corals smaller than 3 cm were not collected in this study.

In situ data were collected along three 20 m x 1 m belt transects at each middle and outer monitoring site, each week during the baseline survey period (October 18-December 30, 2013) when safe diving conditions were present. Scientific divers placed transect tapes, marked in metric and standard units along the pre-established transects, securing the tape at the beginning, mid, and end points. All permanently marked corals were mapped along each transect, their distance along each transect and position to the right (R) or left (L) of the transect line was recorded to assure repeatability in subsequent monitoring events. Baseline *in situ* survey data were collected using underwater data sheets and clipboards. *In situ* baseline data were collected on the abundance (counts) and condition for all scleractinian species (colonies greater than 3 cm) and octocoral genera occurring within the 20m x 1m belt transect during Week 1 of baseline surveys. Additionally, abundance (counts) of sponge morphotypes and zoanthid genera were collected during Week 1. In Weeks 2-4, transects were visually assessed for changes, but no counting of individual octocorals was conducted in Weeks 2-4. Scleractinian data, including counts and condition data, were collected for all weeks where surveys took place. Qualitative sedimentation observations were also collected during *in situ* surveys during each survey.

2.3.3   Coral Condition

Scleractinian corals are sensitive to environmental changes and therefore coral condition is used as an indicator of reef "health" (Vargas-Angel et al. 2007). Coral condition is one of the metrics required by the FDEP permit which may trigger a corrective action should channel-side sites be significantly different than their comparable reference sites. Coral health assessment parameters include any condition that may be expected to adversely affect coral "health". Coral conditions included bleaching, excess mucus production, polyp extension, disease, and sediment accumulation (Bruckner 2001) (Table 2; Figures 5a and b). Each permanently marked coral colony was assessed for each of the health parameters and assigned a condition of either "0" or "1" for each parameter. A score of "0" indicated no observed bleaching, excess mucus production, polyp extension, disease, or other adverse condition, while a "1" would be assigned if one or more condition was present. Conditions scores were not additive, if a coral exhibited more than one condition (e.g., mucus and polyps extended), the coral still received a score of "1".

Table 2: **Coral conditions present at middle and outer reef survey sites during baseline surveys (adapted from Florida Reef Resilience Program (FRRP) and DC&A 2012).**

10
Figure 5a: Photographs of sedimentation indicators collected during baseline surveys.BW1 = baseline week 1; BW4 = baseline week 4.
Figure 5b: Photographs of coral stress conditions collected during baseline surveys.

2.3.4 Photo and Video

Scientific divers collected still photographs of permanently marked corals from a horizontal perspective, so that the largest side of an entire colony was present within a single photo frame along with the permanent marker and scale bar during the baseline monitoring events. Due to the variation in coral size across transects and sites, framers were not used. Additional photographs were collected at the center of the site, adjacent to the sediment block, facing four directions at approximately 1.5 m above the bottom from an oblique angle so that the water column and general site characteristics and landscape were captured in the photographs.

Quantitative digital video data was collected along each transect with the camera positioned 40 cm above the substrate in a vertical orientation to produce birds-eye view digital video of each transect (20 m x 0.4 m), in each week surveyed (Aronson et al. 1994). The video camera was equipped with a measuring device to ensure the camera remains at 40 cm above the bottom and a scale bar is visible at the bottom of the video record at all times (Figure 6). The diver swam the camera along each transect at a speed of ~5 m per minute to insure quality still images could be extracted (frame-grab) for point count analysis using Coral Point Count with extensions (CPCe®) (Kohler and Gill 2006). This method will be used to evaluate both the coral

Figure 6: Scientific diver collecting video data along transects during baseline surveys. Photo taken October 24, 2013

health and potential sedimentation stress during construction as well as functional group cover at both the construction monitoring station and the reference monitoring station.

2.3.5 Sedimentation

Baseline sedimentation data were collected to understand the sediment dynamics at the monitoring sites before the start of dredging. Sediment trap sample collection was completed for all middle and outer reef sites between 26 and 48 days (Table 3). The variation in the number of days of sample collection is due to weather and the ability of scientific divers to safely conduct diving operations. Each sediment trap (3 per site) held three replicate 500mL Nalgene bottles. If one or more bottles were lost or tipped over during the survey period, this was an unusual situation which may have resulted from weather, waves or human interaction. In this case, the sample would have been discarded and a note made in the sample record to alert the sediment sample analysis team. Replicates were combined for analysis so a single estimate per transect was calculated. Sediment samples were collected to determine daily sedimentation rates, and to evaluate the fraction of sediment withheld by a # 230 sieve and the fraction of sediment that passed through the # 230 sieve (fine grain). Baseline sedimentation block data were collected in the 4th week of baseline surveys. Blocks were visually assessed at five points on the block, in each of four corners, and in the center of the block. Still photos of each block were also collected.

Table 3:   Baseline sediment sample collection dates by site.

Site	Date Sediment Collected

2.4   Data Analysis

2.4.1   *In Situ* Data

After *in situ* data collection, scientific divers reviewed their results and discussed issues with the on-site scientific data manager. Underwater data sheets were then cleaned, dried, and quality controlled by the Project Manager, before baseline data were entered into an Excel based spreadsheet program. Parametric and non-parametric statistical methods were used to quantify and describe functional group (e.g., sponge, octocoral, and scleractinian) data. Condition values were calculated from raw data and are presented in the results section of this report. Abundance, density, diversity (H'), and evenness (J') were calculated as follows:

$$Abundance = \frac{Total\ number\ of\ individuals\ for\ a\ species}{Total\ number\ of\ species\ at\ a\ given\ site}$$

$$Density = \frac{Total\ number\ of\ individuals\ for\ a\ species}{Total\ area\ of\ a\ transect}$$

$$Diversity\ (H') = \sum_{j=1}^{\%} p_i\ ln\ p_i$$

$$Evenness\ (J') = \frac{H'}{ln\ S}$$

2.4.2 Coral Condition Data

Coral condition data were analyzed for permanently marked and photographed corals only. In order to accurately and precisely analyze the coral condition data in baseline and beyond, photographs were used to confirm the presence or absence of a condition.

2.4.3 Statistical Error

In statistical testing, false positives (false alarms) correspond to Type I statistical errors and false negatives (defective alarms) correspond to Type II errors (e.g., Gonick and Smith 1993). Until recently, ecologists have been obsessed with avoiding Type I error: falsely concluding that there is an effect when in fact there is none. Concern over Type I error has generally led to ultraconservative testing, which has come at the cost of equally problematic Type II error: falsely concluding that there is no effect when in fact there is one (Aronson and Precht 2006). Therefore, being able to decipher signal from noise is critical in being able to test for Type I and Type II errors. Thus, it is imperative that changes in coral condition through time and space be evaluated with respect to the reference corals and that significant changes (p<0.05) be noted in a timely and responsive manner.

2.4.4 Functional Group Analysis

2.4.4.1 QA/QC of Functional Group Video Analysis

Video analysts conducted quality control exercises prior to evaluating transect documentation. A training dataset of 30 hardbottom images, with 10 random points/image was compiled by two expert analysts for: macroalgae (MACA); crustose coralline algae, turf, and bare (CTB); sediment/sand, pavement, and rubble (SPR); zoanthids (Z); hard coral (C); octocoral/gorgonians (G); and sponges (SPO). All video analysts independently performed a functional group analysis of the training dataset. Image-scoring from each analyst was compared on a per-image basis to the expert results. If an analyst diverged from the expert assessment by more than one point per benthic category, the images were reviewed with the analyst; the difference was discussed and corrected.

2.4.4.2 Video Analysis of Functional Groups

Video documentation collected during the last week of baseline surveys for any given site were analyzed for the baseline report. Video transect footage was segmented (frame grab) into non-overlapping still images using GOM Player™ software. For a 20 m transect, approximately 60 individual still images were generated. Each image was analyzed by using CPCe®, overlaying 10 randomly generated points (Somerfield et al. 2008). The organism or feature underneath each random point on the image was characterized by functional group. Functional groups are as follows: macroalgae (rhodophyta, phaeophyta, chlorophyta, and cyanobacteria); crustose coralline algae, turf, and bare (CTB); sediment/sand, pavement, and rubble (SPR), zoanthids (Z), hard coral (C), Octocoral/Gorgonian (G), and sponge (SPO). Coralline algae, turf, and bare substrate are difficult to differentiate using video techniques and therefore are grouped together for analysis (Aronson et al. 1994).

2.4.5   Sedimentation Analysis

As described above, all three transects within a monitoring site had an associated sediment trap installation that contained three collection bottles. A total of nine bottles collected sediment accumulation data at each monitoring site. For analysis, three replicates (bottles) from the sediment traps were combined to produce an aggregate sample per transect. These three samples were then averaged to create a site mean sedimentation rate. Sedimentation rates were calculated by dividing the sample dry weight value by the number of days the sediment collection bottles were in the water, with the first day being the day after the bottles were installed. Transect values were averaged to calculate a site mean.

The mass of the specimen in each bottle was measured. The sediment samples were washed from the collection bottles through a U.S. Standard No. 230 sieve until water flowed freely through the fraction retained on the sieve. All wash water and sediment passing the No. 230 sieve was collected. The procedure for sediment trap analysis treats organisms that may have grown or crawled (i.e., fish, crabs, worms, algae) into the sediment collection bottle, if visibly retained on the sieve, as sample contaminants and these items were removed during the wash process and noted. No sample contaminants were observed in the baseline sediment trap samples. Sand retained on the No. 230 sieve was washed into a labeled tare. Some of the water was aspirated off the sand fraction and the tare was placed in a forced-draft oven at 66°C (150°F) until dry and for a minimum of 24 hours. Containers with the fraction passing the No. 230 sieve were allowed to settle for a minimum of 48 hours. After settling, the water was aspirated off the settled sample and the fine fraction was consolidated using additional wash water into the appropriate size labeled and weighed container and allowed to settle another 48 hours. The conductivity of the water was measured after the second settling phase. The water was aspirated off and the fraction of sample finer than the No. 230 sieve was placed in the oven until dry and for at least 24 hours. The samples were removed from the oven and placed in the desiccator until cooled.   The mass of the fractions retained and passing the No. 230 sieve were determined and recorded to the nearest 0.01 gram. All the data was entered into an Excel spreadsheet.

2.4.6 Sedimentation Measurement QA/QC

Sedimentation measurements on the blocks were not possible to collect since no sediment accumulated during the baseline period. All personnel were trained to assess the sediment block at four outside corners and in the center of the block using a mm ruler.

3.0   RESULTS

3.1   Quantitative Benthic Sampling

Nine middle reef sites (4 channel-side compliance, 5 reference) and 8 outer reef sites (4 channel-side compliance, 4 reference) were surveyed between 2 and 4 times for benthic community characteristics. Abiotic characteristics (e.g., substrate type and maximum depth), colony counts of scleractinian (by species) and octocorals (by genus) were collected from all transects, as well as condition of scleractinian corals. Additionally, total counts of sponge morphotypes and zoanthid frequencies were collected along each transect. Photos of all permanently marked corals and video of each transect were also collected. Parametric and non-parametric statistics were used to analyze the abundance and density of scleractinians and octocorals, as well as condition of corals. Raw data are presented in table form in Appendix A.

3.1.1   Abiotic Characteristics

3.1.1.1 Middle Reef

All sampling was conducted in areas of middle reef habitat in 6 to 12 m (20 to 40 feet) of water. Hard substrate was typically interspersed with sand pockets (Table 4). Rubble was present at all sites (i.e., R2N1-RR, R2N2-LR, R2NC1-LR, R2NC2-RR, R2NC3-LR, R2S1-RR, R2S2-LR, R2SC1-RR, R2SC2-RR). Photographs representative of the biological benthic communities at each site are presented in Appendix A.

3.1.1.2 Outer Reef

All sampling was conducted in areas of middle reef habitat in 11 to 15 m (34 to 46 ft) of water. Hard substrate was typically interspersed with small sand pockets (Table 5). Rubble was present at 5 of 6 southern sites (i.e., R3S1-CP, R3S2-LR, R3SC1-CP, R3SC2-LR, and R3SC3-SG) and not present north of the channel and at R3S3-SG. Photographs representative of the biological benthic communities and substrate types at each site are presented in Appendix A.

3.1.2   Scleractinian Occurrence

3.1.2.1 Middle Reef

Twenty seven scleractinian coral species were documented across the middle reef sites. Seven sites (i.e., R2N1-RR, R2NC1-LR, R2NC2-RR, R2NC3-LR, R2S1-RR, R2S2-LR, R2SC2-RR) included between 11 and 13 species. At R2SC1-RR, sixteen species were found, and R2N2-LR displayed the highest number of scleractinian species throughout baseline, with seventeen scleractinian colonies documented in Week 4 (Table 6).

Table 6:   Scleractinian species present at each middle reef site for all baseline weeks.

3.1.2.2 Outer Reef

Twenty-five scleractinian coral species were documented across the outer reef sites. Six sites (i.e., R3N1-LR, R3S2-LR, R3S3-SG, R3SC1-CP, R3SC2-LR, and R3SC3-SG) included between 14 and 15 species, while R3NC1-LR had 11 species represented and R3S1-CP contained 10 species (Table 7).

3.1.3 Scleractinian Abundance

3.1.3.1 Middle Reef

Scleractinian colony abundance ranged from 38 (R2N2-LR baseline Week 4) to 147 (R2NC1-LR baseline Week 3) colonies across middle reef sites. R2N2-LR had the highest number of species (17) at a single middle reef site (Table 8). A small proportion of scleractinian species made up the majority of scleractinian colonies at middle reef sites. Across all sites, four species dominated: *Dichocoenia stokesii*, *Montastraea cavernosa*, *Porites astreoides*, and *Siderastrea siderea* (Figure 7 and 8). Two other species, *Stephanocoenia intersepta* and *Solenastrea bournoni*, also contributed to the five most abundant species at one or more sites. The five most abundant scleractinians accounted for 79% of colonies at the northern middle reef sites and 66% of colonies documented at southern middle reef sites. *S. siderea* was the dominant scleractinian coral at the middle reef with cumulative abundances of 26%.

Table 8:   Number of scleractinian colonies and species richness during baseline surveys at middle reef sites.

Site	Number of Colonies		Number of species	*N*
	Mean	SE		
R2N1-RR	82.5	6.0	13	4
R2N2-LR	48.0	8.4	17	4
R2NC1-LR	127.5	9.1	13	4
R2NC2-RR	96.7	9.6	11	3
R2NC3-LR	72.0	13.5	14	3
R2S1-RR	55.0	3.3	12	4
R2S2-LR	47.3	3.6	14	4
R2SC1-RR	71.8	10.4	16	4
R2SC2-LR	47.8	7.5	13	4
Figure 7: Relative abundance of the five dominant scleractinian corals at the northern middle reef sites in Week 4 of baseline surveys.
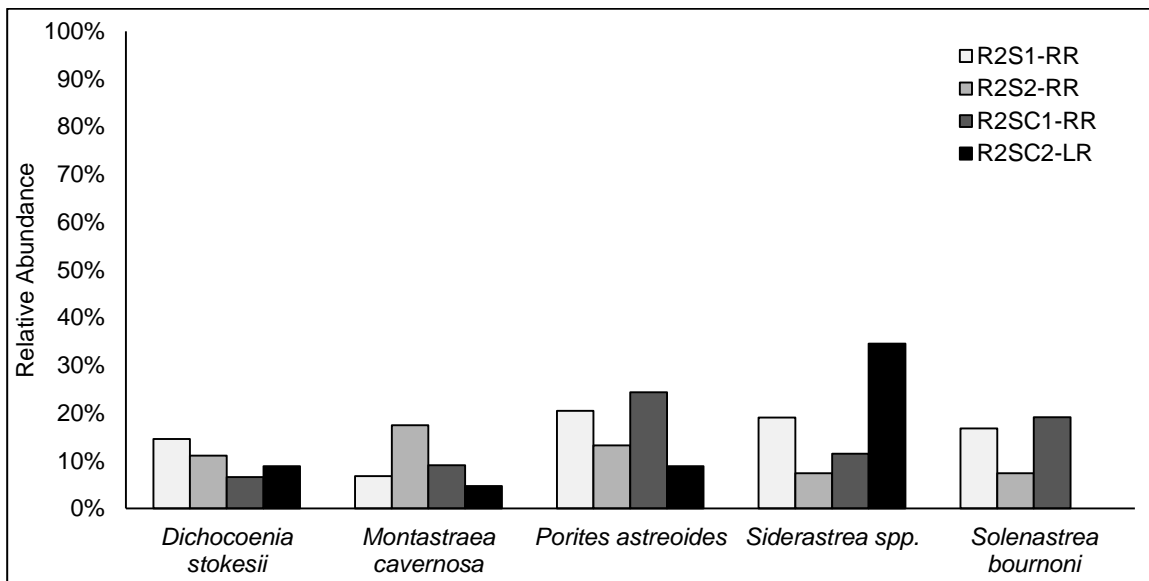

Figure 8: Relative abundance of the five dominant scleractinian corals at the southern middle reef sites in Week 4 of baseline surveys.

3.1.3.2 Outer Reef

Scleractinian colony abundance ranged from 33 (R3S3-SG baseline Week 4) to 225 (R3SC3-SG baseline Week 1) colonies across outer reef sites (Table 9). A small proportion of scleractinian species made up the majority of scleractinian colonies at outer reef sites (e.g., *Montastraea cavernosa*, *Porites astreoides*, *Siderastrea spp., Stephanocoenia intersepta,* and *Solenastrea bournoni*). In some cases it was difficult to differentiate between *S. siderea* and *S. radians*, in these cases, *Siderastrea* sp. was used to describe the colony. *Siderastrea* spp. in this case is all *Siderastrea* species that were described as *S. radians*, *S. siderea* and *Siderastrea* sp. The five most abundant scleractinians accounted for 73% of colonies at the northern outer reef sites and 70% of colonies documented at southern outer reef sites. *P. astreoides* was the dominant scleractinian coral at the outer reef with cumulative abundances of 39% (Figure 9 and 10).

Table 9:   Number of scleractinian colonies and species richness during baseline surveys at outer reef sites.

Site	Number of Colonies		Number of species	*N*
	Mean	SE		
R3N1-LR	47.3	6.4	15	3
R3NC1-LR	52.5	15.5	10	2
R3S1-CP	43.7	8.7	11	3
R3S2-LR	64.0	21.5	15	3
R3S3-SG	51.3	16.4	15	3
R3SC1-CP	82.0	32.7	14	2
R3SC2-LR	96.5	45.3	15	2
R3SC3-SG	139.0	70.2	14	2

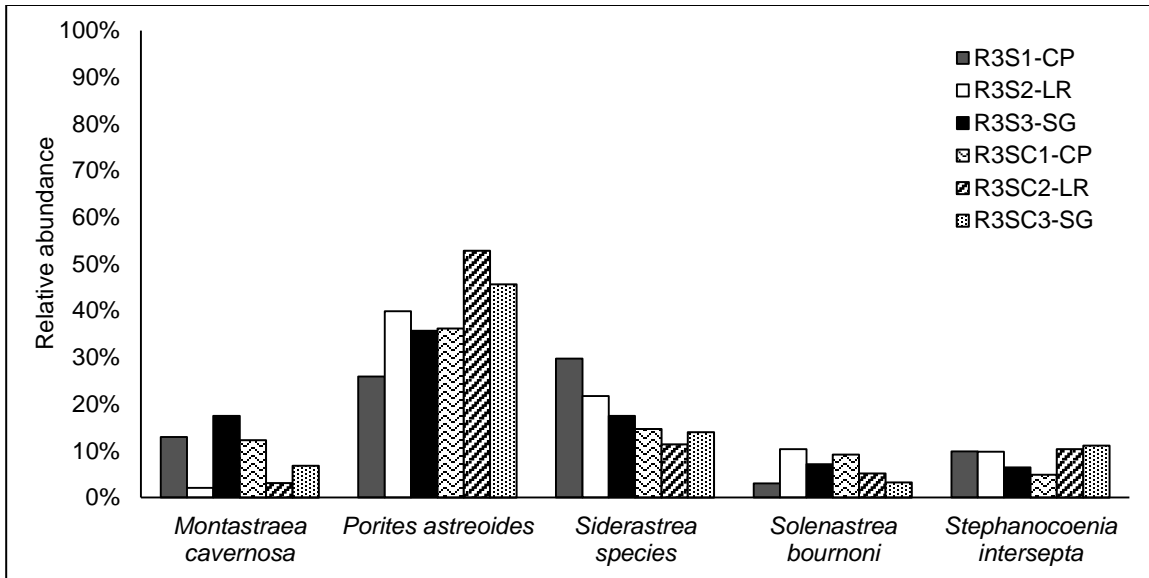

Figure 10: Relative abundance of the five dominant scleractinian corals at the southern outer reef sites during baseline surveys.

3.1.4 Scleractinian Density

3.1.4.1 Middle Reef

Mean scleractinian density ranged from 0.95 to 2.49 colonies per m^2 across all middle reef sites in four weeks of baseline surveys. Mean scleractinian density was lowest at R2S1-RR (0.95 colonies/m^2) and highest at R2SC1-RR (2.49 colonies/m^2) (Figure 11).
Figure 11: Mean density of scleractinian colonies at middle reef sites during baseline surveys. Error bars represent the standard error for each site.

A one-way ANOVA was used to determine if mean coral density was different over the nine middle reef sites. Mean site density, expressed as the mean number of coral colonies per m^2 averaged over the 4 weeks of baseline assessment, were normally distributed (Anderson-Darling tests, $P > 0.05$ in all cases) and the variances were homogeneous (Levene's test, $P =.423$). Significant effects of site were detected ($P =.000$; Table 10). Tukey Honestly Significantly Difference (HSD) post-hoc analysis revealed that the first northern control site (R2NC1) had significantly higher coral density than three of the four of the channel side sites (R2N2, R2S1, R2S2) and one of the southern controls (R2SC2) ($P<0.05$ in all cases). Additionally, one of the southern control sites (R2SC1) had significantly higher coral density than all four channel-side sites (R2N1, R2N2, R2S1, R2S2) and the other southern control site (R2SC2) ($P<0.05$ in all cases). These sites groupings indicate that location of sites in reference to the navigation channel may influence coral density. Average coral density when grouped by location (channel-side vs. control) were normally distributed (Anderson-Darling tests, $P > 0.05$ in both cases), and the variances were homogeneous (Levene's test, $P =.069$). Coral density was found to be significantly higher away from the navigation channel (T-test, $P =.001$). This result shows that some compliance sites are significantly different than their reference or control sites in terms of coral density, but given the design of the study, provide the best comparison available. It is also important to understand that different environmental conditions will be affecting communities adjacent to a channel, which have a very different set of environmental conditions in terms of current, exposure to land based sources of pollution, and turbidity when compared to non-channel habitats. The purpose of the baseline surveys is to document these differences so that they can be taken into account in the post-dredging analysis.

Table 10: ANOVA results testing the difference in scleractinian density over the nine middle reef sites.

Source of variation	df	MS	F	P-value
Between Sites	8	0.882	8.950	0.000
Within Sites	18	0.099		
Total	26			

3.1.4.2 Outer Reef

Mean scleractinian density ranged from 1.03 to 3.51 colonies per m^2 across all outer reef sites in four weeks of baseline surveys. Mean scleractinian density was lowest at R2S1-RR (0.95 colonies/m^2) and highest at R2SC1-RR (2.49 colonies/m^2) (Figure 12).
Figure 12: Mean density of scleractinian colonies at outer reef sites during baseline period. Error bars represent the standard error for each site.

A one-way ANOVA was used to determine if mean coral density was different over the eight sites of the outer reef survey area. Mean site density, expressed as the mean number of coral colonies per m^2 during the baseline assessment, was transformed as the square root of the variable to meet the assumptions of normality and homogeneity of variances required for parametric testing (Anderson–Darling tests, $P > 0.05$ in all cases; Levene's test, $P = .103$). Significant effects of site were detected ($P = .000$; Table 11). Tukey HSD post-hoc analysis revealed that coral density at the third south control site (R3SC3, mean density = 3.51) was significantly higher than all other reef 3 sites ($P < 0.05$ in all cases). Additionally, coral density at the second southern control (R3SC2) was significantly higher than both of the northern sites (R3N1 and R3NC1) as well as R3S1 and R3S3. Mean coral density at the first southern control (R3SC1) was significantly higher than R3N1, R3S1, and R3SC1. Although individual control sites were significantly different than channel side sites, location, when grouped as either channel-side or control was not a significant influence on coral density at outer reef sites (Mann Whitney U test, $P = 0.220$).

Table 11: ANOVA results testing the difference in scleractinian density over the eight outer reef sites.

Source of variation	Df	MS	F	P-value
Between Sites	7	0.262	16.111	0.000
Within Sites	16	0.016		
Error	23			

3.1.5 Scleractinian Colony Size

3.1.5.1 Middle Reef

Maximum diameter data were collected for all scleractinian colonies greater than 3 cm along all transects within the outer reef sites. Scleractinian colony size ranged from 3 cm to more than 35 cm. Coral colony size-class data, presented as proportion of total number of colonies per site, revealed that the majority (37 to 56%) of coral colonies across the middle reef sites were between 10 and 15 cm in diameter (Figure 13 and 14).

Figure 13: Proportion of scleractinian coral colonies by size class at northern outer reef sites during baseline surveys.

Figure 14: Proportion of scleractinian coral colonies by size class at southern middle reef sites during baseline surveys.

3.1.5.2 Outer Reef

Maximum diameter data were collected for all scleractinian colonies greater than 3 cm along all transects within the outer reef sites. Scleractinian diameters ranged from 3 cm to more than 35 cm. Coral colony size-class data, presented as proportion of total number of colonies per site, revealed that the majority (46 to 57%) of coral colonies across the outer reef sites were between 10 and 15 cm in diameter (Figure 15 and 16).
Figure 15: Proportion of scleractinian coral colonies by size class at northern outer reef sites during baseline surveys.
Figure 16: Proportion of scleractinian coral colonies by size class at southern outer reef sites during baseline surveys.

3.1.6 Scleractinian Diversity and Evenness

3.1.6.1 Middle Reef

The Shannon–Wiener Diversity Index (H') was used to calculate species diversity. Diversity (H') values ranged from 1.71 to 2.22 across middle reef sites. R2SC1-RR diversity value (1.71) was lowest when compared to the rest of the middle reef sites. Evenness (J') ranged from 0.27 to 0.40 across middle reef sites and was also lowest at R2SC1-RR (Table 12).

Table 12: Shannon–Wiener Diversity Index (H') and Evenness (J') calculated for scleractinian species at middle reef sites.

Site	H'	J'
R2N1-RR	2.18	0.38
R2N2-LR	2.04	0.37
R2NC1-LR	1.89	0.30
R2NC2-RR	1.76	0.31
R2NC3-LR	2.00	0.35
R2S1-RR	2.10	0.39
R2S2-LR	2.22	0.40
R2SC1-RR	1.71	0.27

3.1.6.2 Outer Reef

The Shannon–Wiener diversity Index (H') was used to calculate species diversity. Diversity (H') values ranged from 1.79 to 1.97 across outer reef sites. R3SC2-LR diversity value (1.79) was lowest when compared to the rest of the outer reef sites. Evenness (J') ranged from 0.34 to 0.42 across outer reef sites and was also lowest at R3SC2-LR in addition to R3SC3-SG (Table 13).

Table 13: Shannon–Wiener Diversity Index (H') and Evenness (J') calculated for scleractinian species at middle reef sites.

3.1.7 Scleractinian Condition

3.1.7.1 Unidentified Coral Disease (UD)

The coral *Solenastrea bournoni* is one of the most common corals in the waters Miami-Dade County. It has long been thought to be one of the most eurytopic of the Atlantic reef building corals, being able to sustain great variations in temperature, light, and salinity. Throughout the project area, numerous colonies of *S. bournoni* started to show outward signs of distress in the late fall of 2013. This included disease-like symptoms with mottled coloration and necrotic tissues (see Figures 17, *S. bournoni*). Corals in the control areas as well as corals within the project corridor appear to be equally affected. In addition, some 20% of colonies throughout the region appear to be infected based on recent reports. In the middle and outer reef survey areas the proportion of corals exhibiting this unknown disease is documented as less than 6% across all sites (Table 14). Dial Cordy & Associates is currently monitoring tagged colonies to see what the overall effect of this disease has on the long-term survivorship of the individual corals. Dial Cordy & Associates are also initiating an applied research program to understand the spread and causality of this coral malady and its impacts on the overall health of the ecosystem.

3.1.7.2 Middle Reef Scleractinian Condition

Fourteen coral stress conditions were documented during baseline surveys at middle reef sites. Most of these conditions were rare and therefore were not analyzed statistically (see Appendix A). Five coral stress conditions predominated across middle reef sites: 1) sediment stress, 2) polyp extension, 3) fish bites, 4) excess mucus and 5) unknown partial mortality. The proportion of corals exhibiting each of these five stress indicators are shown for the northern and southern middle reef sites (Figure 18 and 19 respectively). The unknown partial mortality (UPM) condition was observed in all weeks of baseline surveys and was described as mortality originating from the base of the colony and moving across the colony in a band-like fashion. Two diseases were also reported in the middle reef areas – white plague disease and the unidentified disease of coral species *Solenastrea bournoni*. The white plague disease only occurred in one colony of *Dichocoenia stokesii* at R2N1-LR. The unknown *Solenastrea* disease was widespread (Section 3.1.7.1). An average of 53.2% of scleractinians surveyed exhibited one or more stress conditions.
Figure 18: The average proportion of corals exhibiting the top five stress indicators at the northern middle reef sites.
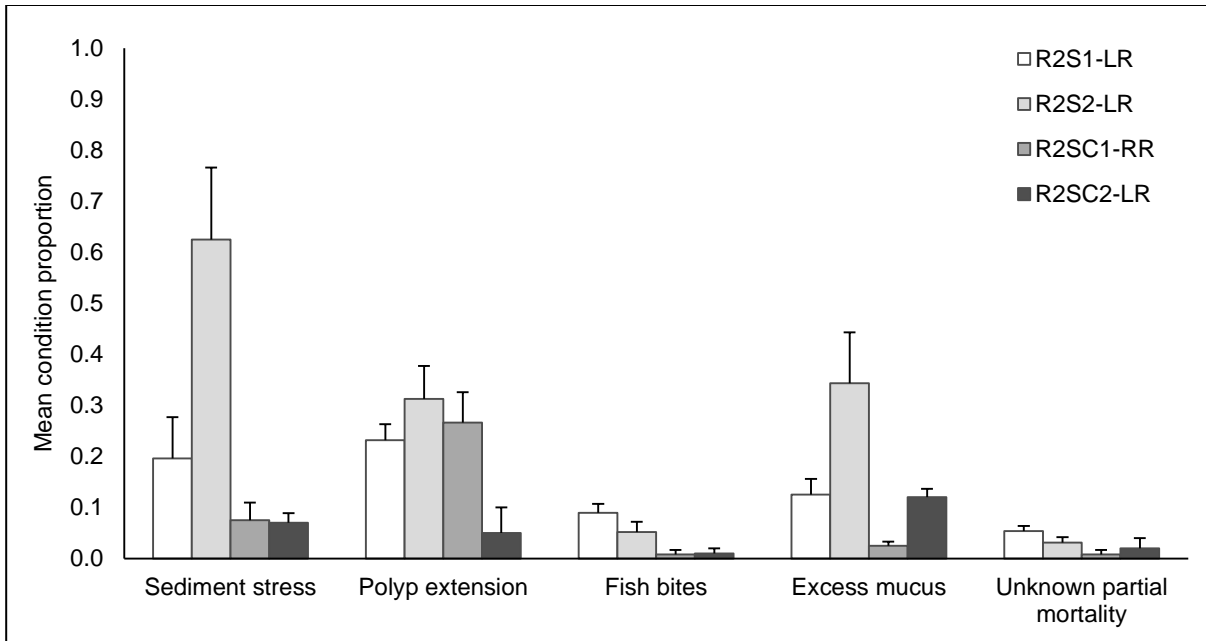

Figure 19: The average proportion of corals exhibiting the top five stress indicators at the southern middle reef sites.

3.1.7.3 Spatial Analysis of Middle Reef Coral Condition

Average coral condition, as measured by the average proportion of stressed corals present in each middle reef transect over the baseline sampling period, was not affected by sampling location (north vs. south of the channel) (Mann-Whitney U, *P*=.486; Figures 18 and 19).

3.1.7.4 Temporal Analysis of Middle Reef Coral Condition

Baseline surveys of the middle reef sites were conducted in concurrent weeks on a per site basis. The 4 weeks of baseline for the first replicate middle reef sites (R2N1, R2S1, R2NC1 and R2SC1) began in mid-October and were completed in mid-November whereas baseline for the remaining five sites (R2N2, R2NC2, R2NC3, R2S2and R2SC2) began in mid-November and were completed in mid-December (Refer to Table 1 for exact sampling dates). As such, temporal trends in condition metrics over the four weeks of baseline sampling were tested separately for the two site groupings described above. The mean proportion of stressed corals at each middle reef site is presented for all four weeks of baseline sampling in Table 15. The mean proportion of stressed corals ranged from 0.24 (R2SC2 week 1) to 1.0 (R2S2 week 3).

Coral condition, as expressed as the proportion of stressed corals in each middle reef transect, changed significantly over the four weeks of baseline assessment for the first replicate sites of the middle reef (Sites R2N1, R2NC1, R2S1 and R2SC1)(Friedman's Test, χ^2(3) = 13.972, *P* = .003). Post-hoc pairwise tests indicated that the proportion of stressed corals at middle reef sites R2N1, R2NC1, R2S1, and R2SC1 increased significantly between Week 1 surveys and Week 3 as well as between Week 1 and Week 4 (P = .034 and .012 respectively, Table 16). The increase in the proportion of stressed corals between mid-October and mid-November is most likely due to the increased frequency of winter storms

beginning on 10/24/2013. A total of 18 of the 38 days between Week 1 and Week 4 were characterized by high wind and wave activity that resulted in small craft condition warnings. Winter conditions including increased turbidity and colder water temperatures may have an impact on the stress levels of corals within the study area.

Temporal changes in the top five condition metrics were also tested over the 4 weeks of the baseline study at sites R2N1, R2NC1, R2S1 and R2SC1. Sediment stress, polyp extension, fish bites, and excess mucus had a large enough sample size to perform weekly significance testing. Of these four metrics, only sediment stress changed significantly over the baseline study (Friedman's Tests, $\chi^2(3) = 20.406$, $p = .000$) (Figure 20, Table 17). Post-hoc pairwise tests indicated that the proportion of corals affected by sediment accumulation in Week 3 was significantly higher than in Week 1 ($P= .000$). Increased sediment mobility and associated coral stress is expected during periods of strong wind and wave activity documented during the baseline study period.

For the middle reef sites that were sampled between mid-November and mid-December (R2N2, R2NC2, R2NC3, R2S2and R2SC2), four weeks of baseline data were only collected for sites R2N2, R2S2, and R2SC2 due to weather constraints and the inability to safely conduct scientific diving operations. All temporal analyses were performed on these sites. Coral condition, as expressed as the proportion of stressed corals in each middle reef transect, changed significantly over the four weeks of baseline assessment for the second replicate sites of the middle reef (Sites R2N2, R2S2, and R2SC2) (Friedman's Test, $\chi^2(3) = 9.40$, $P = .024$). Post-hoc pairwise tests indicated that the proportion of stressed corals at middle reef sites R2N2, R2S2, and R2SC2 increased significantly between Week 1 surveys and Week 4 as well as between Week 2 and Week 4 (P = .014 and .018 respectively, Table 18). The increase in the proportion of stressed corals between mid-November and mid-December may be due to both the persistence of winter storms throughout the area (11 of 24 days of baseline were characterized by high winds and waves) and the increased sedimentation documented at the nearshore hardbottom sites with the commencement of dredging activities that began on 11/20/2013, west of the middle reef stations.

Temporal changes in the top five condition metrics were also tested over the 4 weeks of the baseline study. Sediment stress, polyp extension, fish bites, and excess mucus had a large enough sample size to perform weekly significance testing. Of these four metrics, only polyp extension changed significantly over the baseline study (Friedman's Tests, $\chi^2(3) = 14.524$, $p = .002$) (Figure 21, Table 19). Post-hoc pairwise tests indicated that the proportion of corals with extended polyps increased significantly between Week 1 and Week 3 ($P= .016$).
Figure 20: The weekly proportion of corals exhibiting the top five stress indicators over the four weeks of baseline assessment for Sites R2N2, R2NC2, R2NC3, R2S2, and R2SC2.
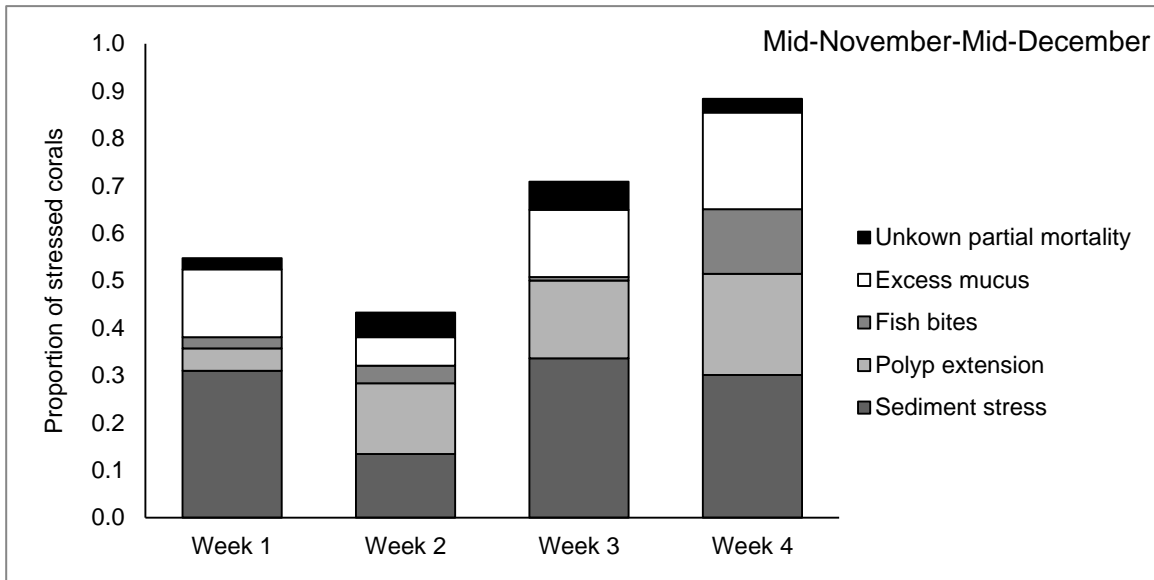

Figure 21: The weekly proportion of corals exhibiting the top five stress indicators at sites R2N2, R2S2, R2NC2, R2NC3, and R2SC2 over the weeks of baseline assessment.

The first baseline assessment of middle reef sites began in Mid-October and concluded in Mid-November prior to the beginning of dredge activity. The second set of baseline assessments of the middle reef was conducted coincident with dredge activity in the nearshore hardbottom area (Cut 2), beginning in mid-November and concluding in mid-December. Sites surveyed during the second baseline assessment period were documented to have suspended sediment in the water column which reduced underwater visibility for the scientific dive team. In addition, sediment accumulation of fine sediment was noted on coral colonies (Table 20, Figure 22).
Figure 22: Photo of *M. cavernosa* colony at R2N2-LR taken on December 15, 2013 showing fine sediment accumulation.

Coral Condition, as measured as the proportion of stressed corals per survey transect was compared across the two groups, those collected in mid-October prior to dredge activity, and those collected while dredge activity was occurring in Cut 2 adjacent to the nearshore hardbottom stations and west of the middle reef compliance stations. There was no significant change in the proportion of stressed corals per survey transect based on sampling time period (Mann-Whitney U, *P*=.544). Although no difference in coral condition was detected, a significant increase in the accumulation of fine sediment was measured on middle reef sites surveyed during dredge activity (Mann Whitney U test, *P*=0.000)).

3.1.7.5 Outer Reef Scleractinian Condition

Ten coral stress conditions were documented during baseline surveys at outer reef sites. Most of these conditions were rare and therefore were not analyzed statistically (see Appendix A). Five coral stress conditions predominated across outer reef sites: 1) sediment stress, 2) polyp extension, 3) fish bites, 4) excess mucus and 5) unknown disease. The proportion of corals exhibiting each of the top five stress indicators are shown for the northern and southern outer reef sites (Figure 23 and 24 respectively). Poor weather and ocean conditions prevented data collection during Week 3 of the baseline assessment so no data are available for that time period. An average of 52.3% of scleractinians surveyed exhibited one or more stress conditions at outer reef sites.
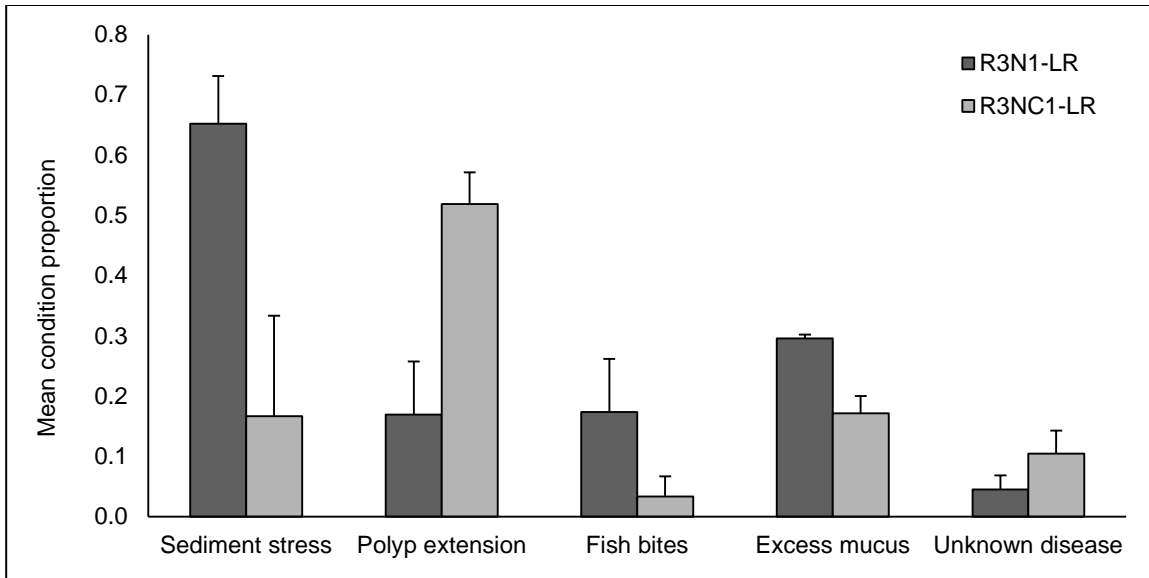

Figure 23: The average proportion of corals exhibiting the top five stress indicators at the northern outer reef sites.
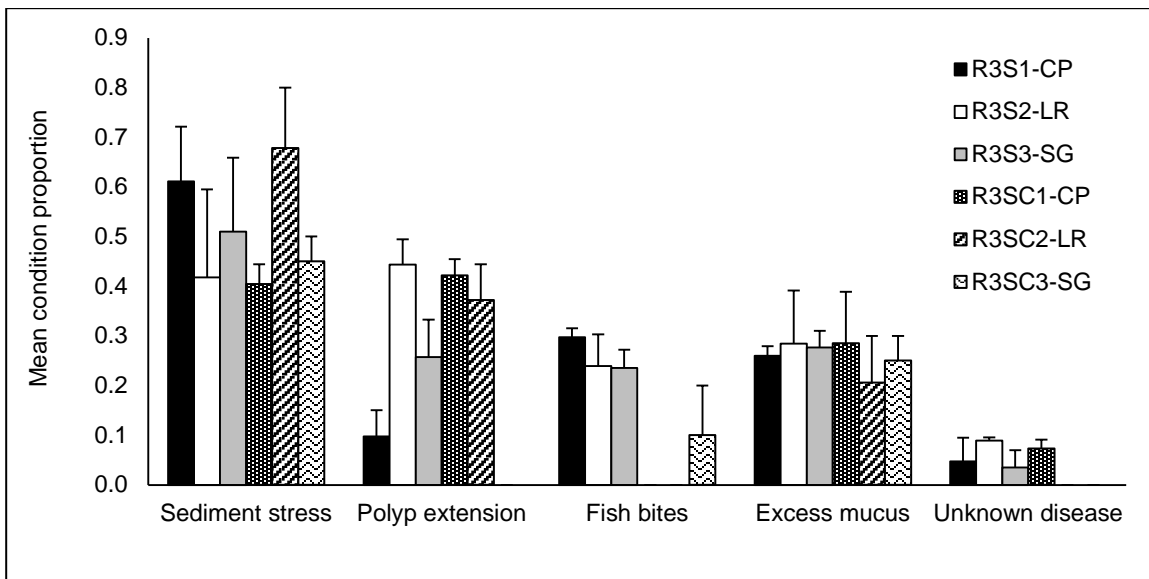

Figure 24: The average proportion of corals exhibiting the top five stress indicators at the southern outer reef sites.

3.1.7.6 Spatial Analysis of Outer Reef Coral Condition

Average coral condition, as measured by the average proportion of stressed corals present in each outer reef transect over the three sampling weeks (Week1, Week 2 and Week 4), was not affected by sampling location (north vs. south of the channel) (Mann-Whitney U, P=.224; Figures 23 and 24). The uneven sampling distribution on outer reef sites (3 compliance sites and 3 control sites in the south and one compliance and one control in the

north) is due to the designation of three habitat types in the south (CP, LR, and SG) and a single habitat type in the north (LR) after Walker (2008).

3.1.7.7 Temporal Analysis of Coral Condition at Outer Reef Sites

Baseline surveys of the outer reef sites were conducted in concurrent weeks at all reef 3 sites. Weather conditions prevented data collection in Week 3 at all sites and at some sites in Week 4. Week 1, 2 and 4 data are only available for sites S3N1, S3S1, S3S2, and S3S3 so the outer reef temporal analysis uses data from only these sites. The mean proportion of stressed corals at all outer reef sites is presented for all four weeks of baseline sampling in Table 21. The mean proportion of stressed corals ranged from 0.37 (R3S1 Week 4) to 0.76 (R3S3 Week 4) at outer reef sites. The overall mean proportion of stressed corals per survey transect is 0.55 in Week 1, 0.48 in Week 2 and 0.56 in Week 4.

Coral condition, as expressed as the proportion of stressed corals in each outer reef transect did not change significantly over the baseline assessment period (Friedman's Test, $\chi^2(2) =$ 1.474, $P = .479$; Figure 25). Winter storm conditions were present on 13 of the 27 days over which the outer reef baseline survey was conducted. By December when the outer reef baseline was completed, winter storm events had been occurring with similar frequency since mid-October.

Temporal changes in the top five condition metrics were also tested over the 3 weeks of the baseline study. Sediment stress, polyp extension, fish bites, and excess mucus had a large enough sample size to perform weekly significance testing. As with total condition, none of the individual metrics of coral stress changed significantly over the baseline study (Table 22, Figure 25).

Table 21: Mean (and standard deviation) of colony condition score over four weeks of baseline data collection at all outer reef sites. Refer to Table 1 for survey dates.

	Week 1		Week 2		Week 3		Week 4

3.1.8   Octocoral Occurrence

3.1.8.1 Middle Reef

Middle reef sites included six to ten octocoral genera. R2N1-RR and R2S2-LR had the highest number of genera (10 genera at each site), whereas R2N2-LR and R2SC1-RR had the fewest (six and seven genera, respectively) (Table 23).

Table 23:   Octocoral genera present at each middle reef site in Week 1 of baseline surveys.

Octocoral genera	Middle Reef Site								
	R2N1-RR	R2N2-LR	R2NC1-LR	R2NC2-RR	R2NC3-LR	R2S1-RR	R2S2-LR	R2SC1-RR	R2SC2-LR

3.1.8.2 Outer Reef

Outer reef sites included four to eight octocoral genera. R3SC1-CP and R3SC2-LR had the highest number of genera (8 genera at each site), whereas R3N1-LR and R3S1-CP had the fewest (five and four genera respectively) (Table 24).

Pterogorgia	•							

3.1.9 Octocoral Abundance and Density

3.1.9.1 Middle Reef

Patterns of octocoral genera relative abundance varied across sites, except that *Eunicea, Gorgonia, and Pseudopterogorgia* were the dominant octocoral genera across all middle reef sites. R2NC1-LP had the greatest number of colonies (510) and genera (8), R2SC2-LR had the least amount of octocorals (191), and R2N2-LR had the fewest genera (6) (Figures 26, and 27 and Appendix A).

Octocoral density ranged from 1.83 to 11.88 colonies per m^2 across all middle reef sites. Across all sites, mean octocoral density was lowest for R2N2-LR (1.83 colonies/m^2) and highest at R2NC3-LR (11.88 colonies/m^2) (Table 25 and Figure 28 and Appendix A).

Table 25: Number of octocoral colonies and generic richness of octocoral colonies at middle reef sites. Data collected during Week 1 of baseline surveys.

Site	Number of colonies	Number of genera
R2N1-RR	696	10
R2N2-LR	47	6
R2NC1-LR	439	8
R2NC2-RR	951	9
R2NC3-LR	126	9
R2S1-RR	156	8
R2S2-LR	131	10
R2SC1-RR	154	8
R2SC2-LR	180	9

Figure 27: Relative abundance of octocorals at the southern middle reef sites in Week 1 of baseline.
Figure 28: Mean density of octocoral colonies across middle reef sites, collected in Week 1 of baseline surveys. Error bars represent the standard error.

3.1.9.2 Outer Reef

Patterns of generic relative abundance varied across sites, except that *Eunicea, Gorgonia, and Pseudopterogorgia* were the predominant octocoral genera across all middle reef sites. R3SC3-SG had the greatest number of colonies (474), R3S1-CP- had the least number of octocorals (84), and the fewest genera along with R3N1-LR (4) (Table 26, Figures 29, 30 and Appendix A).

Octocoral density ranged from 1.40 to 7.9 colonies per m^2 across all outer reef sites. Across all sites, mean octocoral density was lowest for R3S1-CP (1.4 colonies per m^2) and highest at R3SC3-SG (11.88 colonies per m^2) (Table 26 and Figure 31 and Appendix A).

Table 26:   Number of octocoral colonies and generic richness at outer reef sites. Data collected during Week 1 of baseline surveys.

Site	Number of colonies	Number of genera
R3N1-LR	119	4
R3NC1-LR	354	7
R3S1-CP	84	4
R3S2-LR	160	6
R3S3-SG	183	7
R3SC1-CP	220	7
R3SC2-LR	279	7
R3SC3-SG	474	7
Figure 29: Relative abundance of octocorals at northern outer reef sites in Week 1 of baseline.
Figure 30: Relative abundance of octocorals at the southern outer reef sites in Week 1 of baseline.
Figure 31: Mean density of octocoral colonies across outer reef sites, collected in Week 1 of baseline surveys. Error bars represent the standard error.

3.1.10 Octocoral Colony Size

3.1.10.1   Middle Reef

Maximum diameter data were collected for all octocorals along all transects at middle reef sites. Maximum diameter was defined as the maximum linear extent of a colony (cm): height for erect or branching varieties, or diameter for encrusting varieties. Octocoral size-class data reveal that 48% to 72% of colonies across middle reef sites were 5 to 25 cm in maximum diameter (Figure 32 and 33).
Figure 32: Proportion of octocoral colonies by size class for northern middle reef sites during baseline surveys.
Figure 33: Proportion of octocoral colonies by size class for southern middle reef sites during baseline surveys.

3.1.10.2   Outer Reef

Maximum diameter data were collected for all octocorals along all transects within the outer reef sites. Maximum diameter was defined as the maximum linear extent of a colony (cm): height for erect or branching varieties, or diameter for encrusting varieties. Octocoral size-class data reveal that 27% to 67% of colonies across the outer reef sites were 5 to 20 cm in maximum diameter (Figures 34 and 35).

**Figure 34: Proportion of octocoral colonies by size class for northern outer reef sites during baseline surveys.**
Figure 35: Proportion of octocoral colonies by size class for southern outer reef sites during baseline surveys.

3.1.11 Octocoral Diversity

3.1.11.1 Middle Reef

Octocoral generic diversity (H') ranged from 1.34 to 1.85 across middle reef sites and was lowest at R2S2-LR. Evenness (J') ranged from 0.21 to 0.33 across middle reef sites and was also lowest for R2S2-RR. The other site with the lowest J' was R2NC3-LR, which had the same value as R2S2-RR (0.21 (Table 27).

Table 27: Shannon–Wiener Diversity Index (H') and Evenness (J') calculated for octocoral genera at middle reef sites.

Site	H'	J'
R2N1-RR	1.60	0.24
R2N2-LR	1.54	0.33
R2NC1-LR	1.79	0.29
R2NC2-RR	1.78	0.24
R2NC3-LR	1.38	0.21
R2S1-RR	1.65	0.33
R2S2-LR	1.34	0.21
R2SC1-RR	1.57	0.26
R2SC2-LR	1.85	0.28

3.1.11.2 Outer Reef

Octocoral generic diversity (H') ranged from 1.34 to 1.85 across middle reef sites and was lowest at R2S2-LR. Evenness (J') ranged from 0.21 to 0.33 across middle reef sites and was also lowest for R2S2-RR. The other site with the lowest J' was R2NC3-LR, which had the same value as R2S2-RR (0.21) (Table 28).

Table 28: Shannon–Wiener Diversity Index (H') and Evenness (J') calculated for octocoral genera at middle reef sites.

Site	H'	J'
R3N1-LR	0.77	0.16
R3NC1-LR	1.14	0.19
R3S1-CP	0.61	0.14
R3S2-LR	0.87	0.17
R3S3-SG	1.03	0.20
R3SC1-CP	1.19	0.22
R3SC2-LR	1.00	0.18
R3SC3-SG	0.95	0.15

3.1.12 Sponge Presence & Density

3.1.12.1   Middle Reef

Sponge morphotypes were widespread across middle reef sites, ranging from 7 to 5 morphotypes present at any given site (Table 29). *Xestospongia* could only be found at 4 of 9 sites (i.e., R2N2-LR, R2NC1-LR, R2NC3-LR, and R2SC2-LR, Figure 367). No *Cliona delitrix* was found at R2SC1-RR. Sponge density ranked second amongst functional group categories (e.g., scleractinian, octocoral, sponge, zoanthid) and ranged from 2.82 (R3SC1-RR) to 21.8 (R2N2-LR) individuals per square meter.

Table 29:   Sponge morphotype presence at middle reef sites during baseline surveys.

Figure 36: Sponge density values for middle reef sites during baseline surveys. Error bars represent the standard error of the mean.

3.1.12.2   Outer Reef

Sponge morphotypes were widespread across outer reef sites and present at all sites with the exception of *Cliona*, which only occurred in 6 of 8 sites (R3N1-LR, R3NC1-LR, R3S1-CP, R3S2-LR, R3S3-SG, R3SC1-CP, R3SC2-LR, and R3SC3-SG, Table 30, Figure 37). Sponge density ranked second behind octocorals as the most dominant functional group category and ranged from 2.62 (R3S1-CP) to 8.18 (R3N1-LR) individuals per m^2.

Table 30: Sponge morphotype presence at middle reef sites during baseline surveys.

3.1.13 Zoanthid Presence & Density

3.1.13.1 Middle Reef

The zoanthid, *Palythoa*, was the only occurring zoanthid and was widespread in high densities across middle reef sites. R2SC2-LR was documented with exceptionally high *Palythoa* densities, which averaged 3.75 individuals per m^2 across the monitoring station transects. No zoanthids were reported at R2S1-RR and R2SC1-RR (Table 31, Figure 38).

Table 31: Zoanthid presence at middle reef sites during baseline surveys.

3.2 Functional Group Percent Cover

3.2.1 Middle Reef

Functional group percent cover was highly variable across monitoring sites in the middle reef areas. The benthic composition of the northern sites consisted mostly of crustose coralline algae, turf, and/or bare substrate (CTB). In addition to CTB, gorgonians accounted for a large percentage of the benthic cover at R2N1-RR and R2NC3-LR. Zoanthids accounted for a larger amount of cover at R2NC1-LR and R2NC2-RR. Sandy substrate was a predominant feature at R2N2-LR, R2NC1-LR, and R2NC2-RR (Section 3.1) and R2NC2-RR exhibited the highest percentage of coral cover (2.55%) for the northern survey sites (Figure 40). While sand and CTB was also the primary functional group at southern middle reef sites, the southern control sites (R2SC1-RR and R2SC2-LR) had the highest percentage of octocoral cover (22.47% and 21.82% respectively) and zoanthids (10.23% and 11.36% respectively) across all middle reef sites. Scleractinian corals had the highest percentage of cover at R2S2-LR (1.51%) In addition, R2S2-LR showed the highest percent coverage of sponges (4.99%) (Figure 41).
Figure 40: Functional group percent cover for northern middle reef survey sites during baseline surveys.
Figure 41: Functional group percent cover for southern middle reef survey sites during baseline surveys.

3.2.2 Outer Reef

Functional group percent cover was highly variable across outer reef monitoring sites. The benthic composition of all sites consisted mostly of crustose coralline algae, turf, and/or bare substrate (CTB). In addition to CTB, gorgonians and sponges accounted for a large percentage of the benthic cover, ranging from 2.1 to 16.4% across all outer reef sites. Zoanthid cover was greatest (16.4%) at R3S1-CP and sandy substrate accounted for 26.3% of benthic cover at R3NC1-LR. Coral cover was low across all outer reef sites, ranging from 0.14 (R3S1-CP) to 1.22% (R3S3-SG) (Figures 42 and 43).
Figure 42: Functional group percent cover for northern outer reef survey sites during baseline surveys.
Figure 43: Functional group percent cover for southern outer reef survey sites during baseline surveys.

3.3 Sedimentation Rates

The sediment traps held three replicate 500mL Nalgene bottles. In the unusual event of a sediment trap being lost or tipped over due to weather, waves, or human activity, the sample would have been discarded and a note made in the sample record to alert the sediment sample analysis team. Replicates were combined for analysis so a single estimate per transect was calculated. Sediment samples were collected to determine daily sedimentation rates, and to evaluate the fraction of sediment withheld by a # 230 sieve (coarse grained) and the fraction of sediment that passed through the # 230 sieve (fine grain).

3.3.1 Middle Reef

Sedimentation samples were collected from the sediment traps (N = 77) at each transect at the end of the baseline survey period or when weather conditions permitted safe scientific dive operations (24 to 89 days after sediment bottles were placed on site). In the case of the northern reference sites, which were five miles away, baseline samples were not collected until 38 (R2NC1-LR), 88 (R2NC3-LR) and 89 (R2NC2-LR) days after installation due to safety. Coarse-grain sedimentation rates (g/day) were highest at north channel-side sites R2N1-RR (1.81 g/day) and R2N2-LR (1.77 g/day), and lowest at north reference sites R2NC1-LR (0.87 g/day), R2NC2-RR (0.07 g/day) and R2NC3-LR (0.05 g/day). Channel-side sites may have different sedimentation rates when compared to reference sites as their water quality and hydrodynamic environment are very different from natural reef settings. Fine-grain sedimentation rates followed the same pattern as coarse grain sedimentation rates at northern sites. Fine grain sedimentation rates ranged from 0.19 g/day (R2NC3-LR) to 0.71 g/day (R2N2-LR). Southern channel-side sites and southern reference sites had similar sedimentation rate values, although southern reference sites had slightly higher coarse grain sedimentation rates when compared to channel-side sites. At southern sites, coarse-grain sedimentation ranged from 0.51 g/day (R2S1-RR) to 0.80 g/day (R2SC2-LR) and fine-grain sedimentation ranged from 0.42 g/day (R2SC1-RR) to 0.61 g/day (R2SC2-LR). See Appendix A for sedimentation raw data.
Figure 44: Daily sedimentation rates at middle reef sites for coarse-grain sediment (≥ No. 230 sieve). Error bars represent the standard error.
Figure 45: Daily sedimentation rates at middle reef sites for fine-grain sediment (≤ No. 230 sieve). Error bars represent the standard error.

3.3.2 Outer Reef

Outer reef sedimentation samples were collected from sediment traps (*N* = 112) at each transect at the end of the baseline survey period (26 to 75 days after installation) for both reference and channel-side sites. Dredging had already started near hardbottom sites when baseline surveys commenced at outer reef sites.

Coarse-grain (≥ No. 230 sieve) sedimentation rates at outer reef sites (0.04 to 0.09 g/day) were relatively low compared to middle reef sites (Figures 44 and 46). Fine-grain sedimentation (≤ No. 230 sieve) ranged between 0.07 and 0.17 g/day at all outer reef sites and were low when compared to middle reef sites (Figures 45 and 47). This result suggests different hydrodynamics and transportation may affect outer reef sites when compared to middle reef sites.

Miami Harbor Phase III Quantitative   Dial Cordy and Associates Inc.
Baseline for Middle and Outer Reef Benthic Communities   REVISED April 16, 2014

Figure 46: Daily sedimentation rates at outer reef sites for coarse-grain sediment (≥ No. 230 sieve). Error bars represent the standard error.
Figure 47: Daily sedimentation rates at outer reef sites for fine-grain sediment (≤ No. 230 sieve). Error bars represent the standard error.

3.3.3   Sedimentation Blocks

No sediment was recorded at any blocks during the baseline at any sites. Currents and wave action in these areas (channel-side and reference) keep smooth surfaces, such as painted cement blocks free of sediment. Any sediment that may fall on blocks is removed immediately by normal currents and wave action.

4.0   SUMMARY

The Miami Harbor Deepening Project was designed to widen and deepen the outer entrance channel to increase access to the Port of Miami by larger vessels, including post-Panamax vessels. The project was permitted through the Florida Department of Protection (FDEP), under Permit No. 0305721-001-BI. Permit conditions provide a number of protective measures to ensure the preservation of natural resources, such as hardbottom, reef, and seagrass communities, including methods on environmental monitoring required before, during, and after dredging activities.

Baseline surveys presented in this report establish information on the population dynamics, condition and sedimentation environment of the middle and outer reef benthic communities adjacent to the Miami Harbor Phase III Federal Channel Expansion Project area. Middle reef sites included four compliance sites (R2N1-RR, R2N2-LR, R2S1-RR, and R2S2-LR) and five control sites (R2NC1-LR, R2NC2-RR, R2NC3-LR, R2SC1-RR, R2SC2-LR). Outer reef sites included four compliance sites (R3N1-LR, R3S1-CP, R3S2-LR, and R3S3-SG) and four control sites (R3NC1-LR, R3SC1-CP, R3SC2-LR, and R3SC3-SG). Three transects were established and sampled within each site, for a total of 51 transects covering 1020 m^2 of middle and outer reef habitat. Along each transect up to ten scleractinan corals were permanently marked for monitoring before, during, and after dredge activity. Abiotic characteristics (e.g., substrate type and maximum depth), colony counts of scleractinian corals (by species) and octocorals (by genus) were collected from all transects, as well as condition of scleractinian corals. In addition, total counts of sponge morphotypes and zoanthids were collected along each transect. Photos of all permanently marked corals and video of each transect were also collected. Parametric and non-parametric statistics were used to analyze the abundance and density of scleractinians and octocorals, as well as condition of corals.

Middle reef sites included 11-17 coral species, with colony density ranging from 0.95 to 2.49 colonies/m^2 across all sites (including controls). Channel side sites had significantly lower coral colony density when compared to control sites, away from the channel. The greatest proportion of corals were in the size class 10-15 cm, followed by corals in the 3-9 cm size class. Coral condition was high at middle reef sites with 53.2% of corals displaying one or more indicators of coral stress during baseline surveys. Eight to ten genera of octocorals were present across middle reefs sites and density ranged from 1.83 to 11.88 colonies/m^2 across sites. Octocorals were most commonly in the 5-20 cm size range across all middle reef sites. The top three cover categories according to functional group analysis were crustose turf and bare (CTB), octocorals, and zoanthids at middle reef sites.

Outer reef sites included 10-15 coral species, with colony density ranging from 1.03 to 3.51 colonies/m^2 across all sites (including controls). In contrast to middle reef sites, channel side versus control is not a significant influence on coral density at outer reef sites. The greatest proportion of coral colonies at outer reef sites are in the 10-15 cm size range. Coral condition was high at outer reef sites with 52.3% of corals displaying one or more indicators of coral stress during baseline surveys. Four to seven octocoral genera were identified at outer reef sites and octocoral density ranged from 1-8 colonies/m^2 across outer reef sites. Octocorals of the 5-20 cm size range were most common across all outer reef sites. The top three functional group categories at outer reef sites were CTB, octocorals, and sponges.

Throughout the project area, numerous colonies of *S. bournoni* started to show outward signs of distress in the late fall of 2013. This included disease-like symptoms with mottled coloration and necrotic tissues. Six percent of corals at middle reef sites and five percent of outer reef corals were documented this unknown disease during baseline surveys. We are following marked corals to understand the spread and causality of this coral malady and its impacts on the overall health of the ecosystem.

Baseline sediment sampling at middle and outer reef sites was conducted before dredging and while dredging was on going in the hardbottom areas. Middle reef sedimentation rates ranged from 0.05 to 1.81 g/day for coarse grained sediments (≥ 230 sieve fraction), and between 0.19 to 0.71 g/day for fine grained sediment (≤ 230 sieve fraction).Sedimentation rates at outer reef sites were low compared to middle reef sites with coarse-grain sedimentation ranging between 0.04 and 0.09 g/day, and fine-grain sedimentation ranging between 0.07 and 0.17 g/day.

These baseline results will be used as a point of comparison for the post-construction survey to document changes attributable to dredging while considering other environmental or anthropogenic factors that influence middle and outer reef resources in the area.

5.0 RECOMMENDATIONS

- Continue to document and assess the presence of unknown *Solenastrea bournoni* disease throughout the study area.

- Consider eliminating sediment blocks as a tool for measuring sediment accumulation of hardbottom and reef environments, normal currents and wave action keep these blocks free of any sediment accumulation.

- Conduct baseline surveys during summer months when sea state conditions may be better suited for safe scientific diving operations.
